

# Recover from Namenode failure

For online Hadoop training, send mail to [neeraj.ymca.2k6@gmail.com](mailto:neeraj.ymca.2k6@gmail.com)

# Agenda

What is Namenode

Responsibility of Namenode

Single point of failure

Causes of Namenode failures.

Namenode recovery

Role of Secondary Namenode

FsImage & Edits files.

Checkpoints in Hadoop

Creating checkpoints

Recovery with the help of checkpoint

# What is Namenode

Namenode is a process which runs on master machine of Hadoop cluster.

We need to contact Namenode for any read/write operation in HDFS.

Namenode keeps metadata of the data which is stored in HDFS.

Namenode coordinates with datanodes to read/write data in HDFS.

# Responsibility of a Namenode

Namenode keeps a block map of all the files in HDFS.

It contacts each datanode & ask for block report.

It creates bigger block report from all datanode block reports.

It keeps list of live nodes & dead nodes.

It balances the storage of Hadoop cluster.

# Single point of failure

Namenode is single point of failure in Hadoop cluster.

Hadoop cluster is not accessible if Namenode is down.

We can't do any read/write operation, even datanodes have all the data.

Hot backup is not yet supported in Hadoop.

# Causes of Namenode failure

Master machine can stop working due to hardware problem.

Namenode metadata can get corrupt.

Without metadata, Namenode is not capable of finding the data in HDFS.

We can't contact Datanode directly for data.

Checkpoint can be used to recover metadata.

# Namenode recovery

Namenode must be recovered in order to access HDFS.

Hadoop cluster will remain offline, until we recover Namenode.

Secondary Namenode can help Namenode to recover.

We can only recover till the last checkpoint saved.

Stale data is far better than no data.

# Role of Secondary Namenode

Secondary Namenode must be on separate machine in Hadoop production cluster.

Add the following entry in **hdfs-site.xml** to run Secondary Namenode on another machine.

```
<property>  
  <name>dfs.secondary.http.address</name>  
  <value>192.168.1.2:50090</value>  
  <description>The secondary Namenode address and port </description>  
</property>
```

Checkpoints, which are stored on Secondary Namenode, helps in Namenode recovery.

# FsImage & Edits files

FsImage contains snapshot of HDFS metadata.

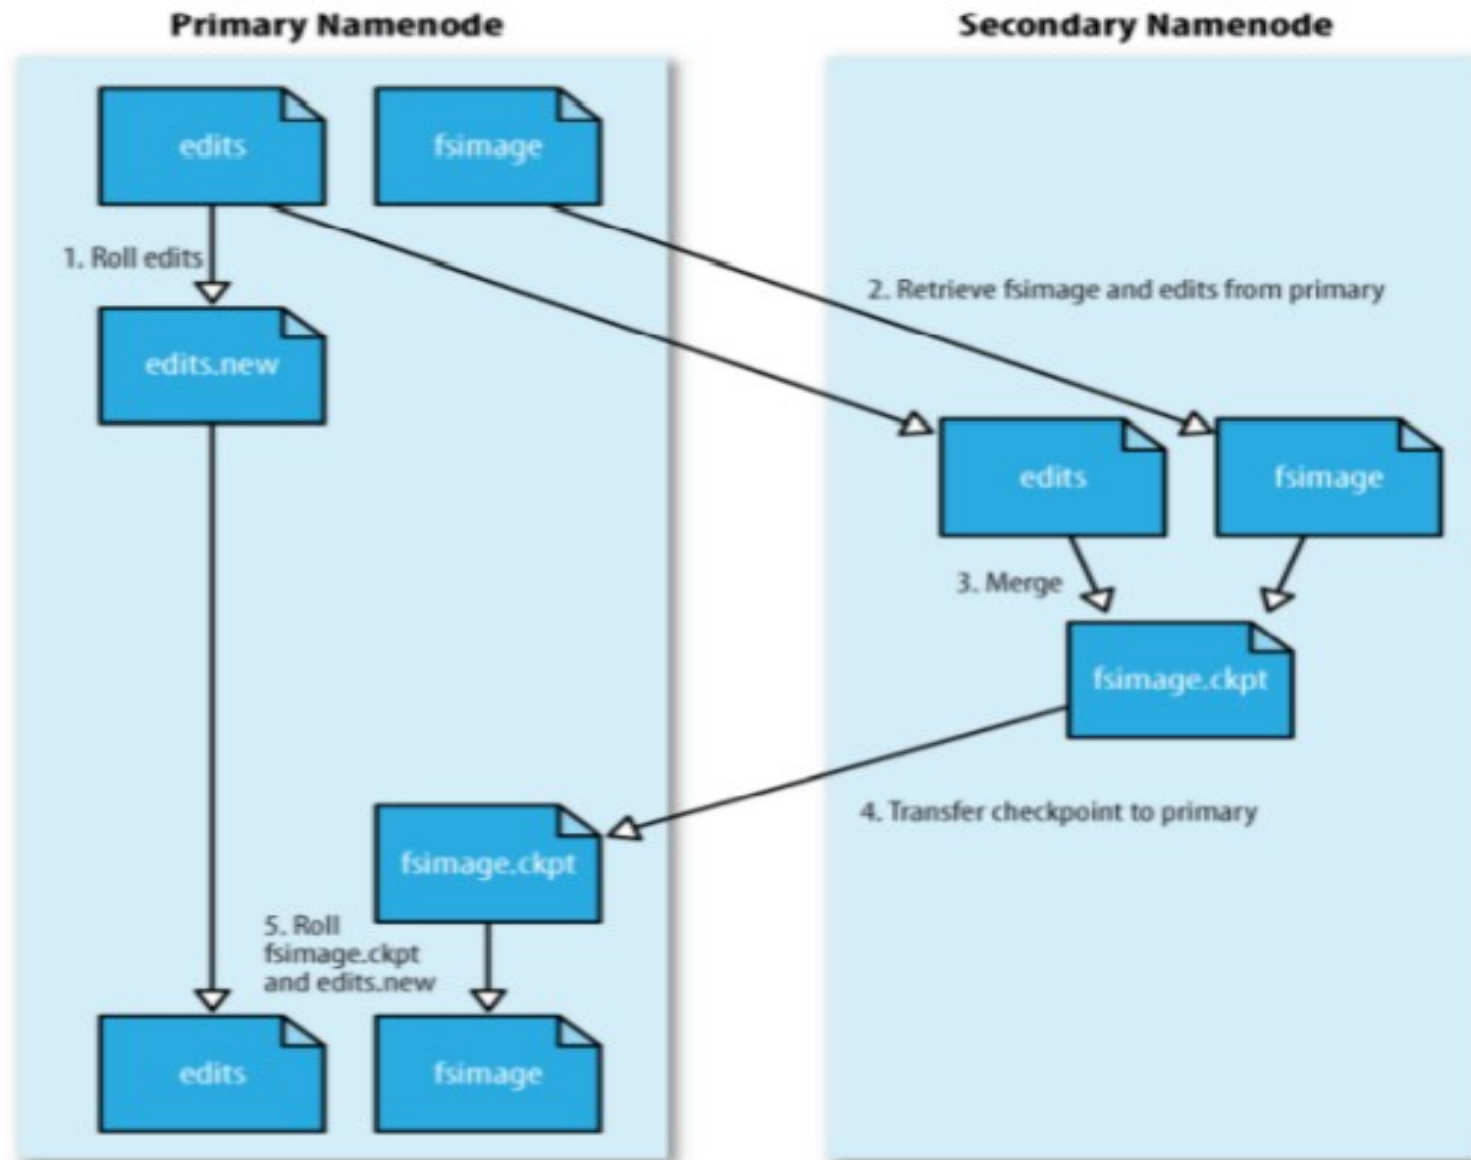

Namenode loads FsImage at its startup.

After every read/write operation, FsImage is not updated.

Instead, all the changes are recorded in edits file.

Later, a new FsImage can be created by merging old FsImage & edits file.

# FsImage & Edits files

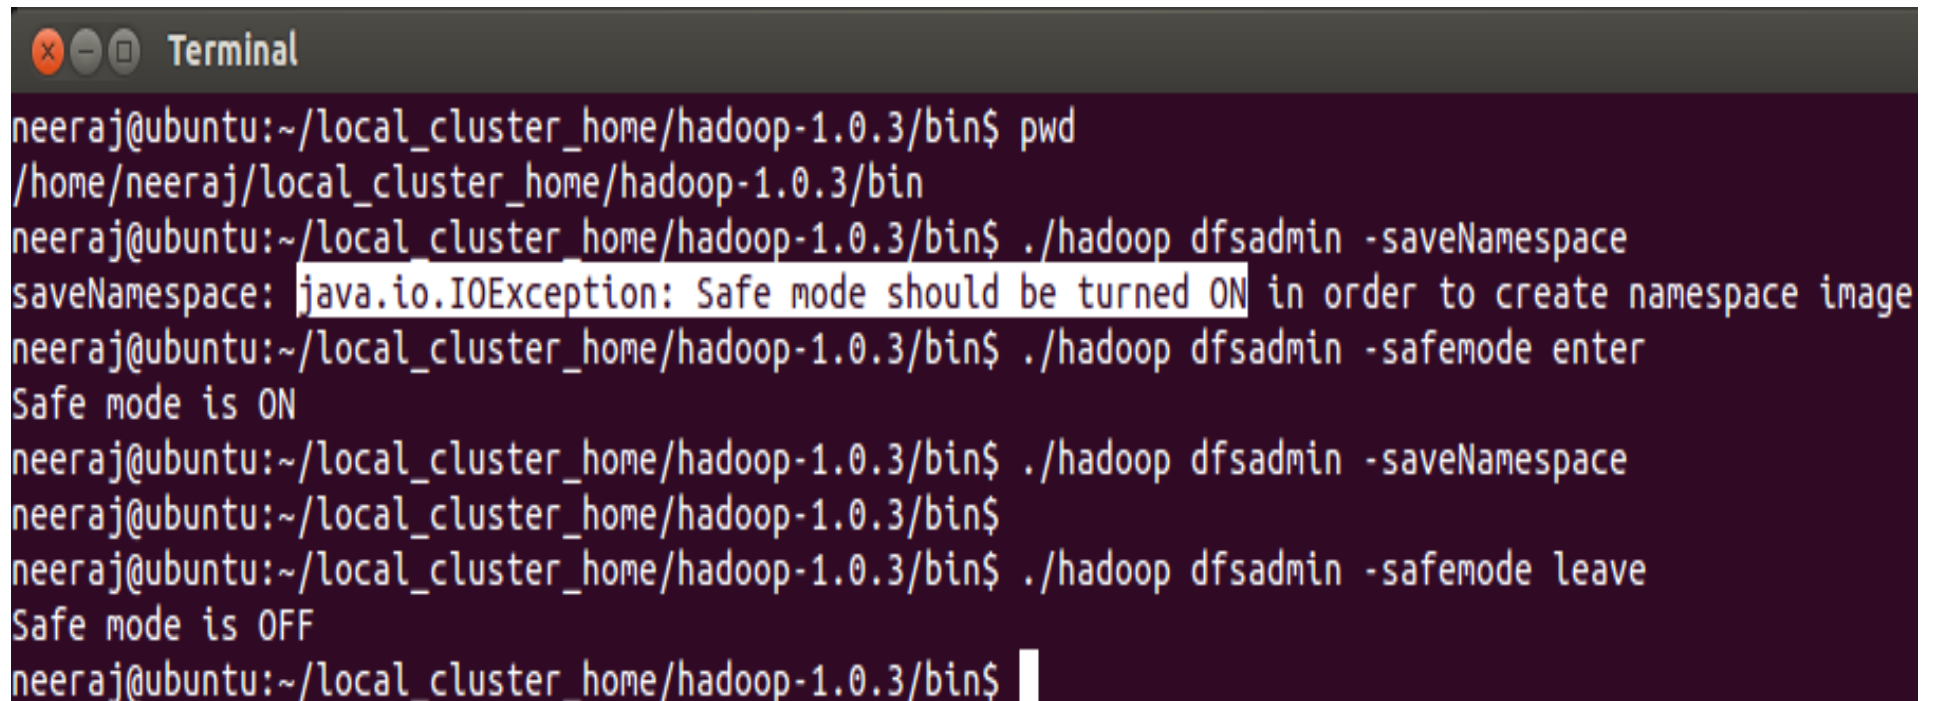

# Creating checkpoints

Checkpoints are taken after every 1 hour ( by default )

Checkpoint are useful for recovering from failure.

We can create checkpoints, by running the below command

```
Terminal
neeraj@ubuntu:~/local_cluster_home/hadoop-1.0.3/bin$ pwd
/home/neeraj/local_cluster_home/hadoop-1.0.3/bin
neeraj@ubuntu:~/local_cluster_home/hadoop-1.0.3/bin$ ./hadoop dfsadmin -saveNamespace
saveNamespace: java.io.IOException: Safe mode should be turned ON in order to create namespace image
neeraj@ubuntu:~/local_cluster_home/hadoop-1.0.3/bin$ ./hadoop dfsadmin -safemode enter
Safe mode is ON
neeraj@ubuntu:~/local_cluster_home/hadoop-1.0.3/bin$ ./hadoop dfsadmin -saveNamespace
neeraj@ubuntu:~/local_cluster_home/hadoop-1.0.3/bin$
neeraj@ubuntu:~/local_cluster_home/hadoop-1.0.3/bin$ ./hadoop dfsadmin -safemode leave
Safe mode is OFF
neeraj@ubuntu:~/local_cluster_home/hadoop-1.0.3/bin$
```

# Checkpoints in Hadoop

Checkpoint are stored in below shown directory

Fsimage is used to recover the namenode

# Recovery with the help of checkpoint

Follow below mentioned steps to recover namenode

1. Stop Hadoop by running `./stop-all.sh` command
2. Copy **fsimage** file from checkpoint directory to current directory.
3. Start hadoop by running `./start-all.sh` command

...Thanks...
